Preface

Abstract

This is an abstract.

Declaration

I declare that this dissertation represents my own work except where otherwise stated.

Acknowledgements

I would like to thank my supervisor Leo Freitas for supporting, guiding, and providing with areas of improvement for me throughout the project.

Chapter 1

Introduction

1.1 Scene

Designing aviation checklists is difficult and requires time to test them in simulators and the real world. [1] The simulators require trained pilots to test the checklist and make sure that they work consistently [2]; testing that the steps in the checklist are concise, achieves the goal of the checklist, and will not take too long to complete to the point it could compromise the safety of the aircraft. These checklists are also carried out by the crew in high workload environments, where this workload would be elevated if an emergency were to occur. [3]

1.2 Motivation

Testing procedures in checklists is often neglected by designers. [1] This is shown in historic incidents, where the checklists to aid resolve the problem at the time was not fit for the specific scenario that crew was in.

An example of this is the checklist used on US Airways Flight 1549. This flight suffered a dual engine failure due to a bird strike at an altitude of 2818 ft (859 m). The first action by the pilot was to turn on the Auxiliary Power Unit (APU), allowing critical systems, such as the flight controls and navigational aids, to be powered as the engines were no longer able to power those systems. However, if the first call was to run through the dual engine failure checklist (the one used on the flight), it would have been the 11th item on the checklist. Using the checklist from the beginning could have resulted in a worse outcome of the incident, but due to the crew's experience, they managed to execute the most successful ditching (water landing) in history. [4]

Therefore, this calls for a way to implement a way to test checklists for aspects that may have been overlooked during the development of the checklist.

1.3 Aim

The goal of this project is to test checklists in Quick Reference Handbooks (QRH) for flaws that could compromise the aircraft and making sure that the tests can be completed in a reasonable amount of time by pilots. It is also crucial to make sure that the tests are reproducible in the same flight conditions and a variety of flight conditions.

1.4 Objectives

- 1. Research current checklists that may be problematic and are testable in the QRH tester being made
- 2. Implement a formal model that runs through checklists, with the research gathered, to produce an accurate test

- (a) Understand the relative states of the aircraft that need to be captured
- (b) Ensure that the results of the checklist procedures are consistent
- 3. Implement a QRH tester manager that
 - (a) Runs the formal model and reacts to the output of the formal model
 - (b) Connect to a flight simulator to run actions from the formal model
 - (c) Implement checklist procedures to be tested, run them, and get feedback on how well the procedure ran

Chapter 2

Background

2.1 Hypothesis

- Checklists can be tested in a simulated environment to find flaws in checklist for things like
 - Can be done in an amount of time that will not endanger aircraft
 - Provides reproducible results
 - Procedures will not endanger aircraft or crew further (Crew referring to Checklist Manifesto with the cargo door blowout)
- Results in being able to see where to improve checklists

2.2 Safety in Aviation

2.2.1 History

- 70-80% of aviation accidents are attributed to human factors [5]
- The first use of a checklist was in 1935 after the crash of a prototype plane known back then as the Model 299 (known as the Boeing B-17 today), due to the complex procedures required to operate the aircraft normally and forgetting a step resulting in lack of controls during takeoff [2]
- It was found that because of the complicated procedure to operate the aircraft that the pilots would forget steps, and hence the concept of checklists was tested, and found to minimize human errors [2]

2.2.2 Checklists

Checklists are defined by the Civil Aviation Authority (CAA), the UK's aviation regulator, as: 'A set of written procedures/drills covering the operation of the aircraft by the flight crew in both normal and abnormal conditions. ... The Checklist is carried on the flight deck.' [6] These checklists as a result has shown to be a crucial tool in aviation to minimize human errors. [2]

There are multiple checklists that are designed for aircraft for the use of normal operation and potential problems that could arise during the flight. These checklists are stored in a Quick Reference Handbook (QRH) which is kept in the cockpit of each aircraft for use when needed. The definition of a QRH by CAA is:

A handbook containing procedures which may need to be referred to quickly and/or frequently, including Emergency and Abnormal procedures. The procedures may be abbreviated for ease of reference (although they must reflect the procedures contained in the AFM¹). The QRH is often used as an alternative name for the Emergency and Abnormal Checklist. [6]

However, checklists themselves can have design flaws as noted by researchers at the National Aeronautics and Space Administration (NASA) where checklists can be misleading, too confusing, or too long to complete, as a result having the potential of compromising the safety of the aircraft. [1] An example of this is what happened on Swiss Air Flight 111, where an electrical fault was made worse by following the checklist, resulting in the aircraft crashing in the ocean. This was as the flight crew was unaware of the severity of the fire caused by the electrical fault. Following the steps in the checklist, one of the steps was to cut out power to 'non-essential' systems, which increased the amount of smoke in the cockpit. Simultaneously, the checklist itself was a distraction as it was found to take around 30 minutes to complete in testing during the investigation. [7] This incident shows that checklists need to be tested for these flaws, and considering the original checklist for Swiss Air Flight 111 would have taken 30 minutes to theoretically complete, this could be timeconsuming for checklist designers, and this would be something to note whilst working on this project.

There are other potential problems with checklists, noted by the CAA, where the person running through the checklist could skip a step either unintentionally, by interruption, or just outright failing to complete the checklist. Or the crew may also not be alerted to performance issues within the aircraft, which would be a result of running the checklist. [6] Therefore, this would be useful to add for features when testing checklists, such as adding the ability to intentionally skip a step of a checklist or gathering statistics on how the performance of the aircraft has been affected as a result of using the checklist.

Another problem to note about checklists is the human factor where the crew may fail to use the checklist, like in the case of Northwest Airlines Flight 255, where the National Transportation Safety Board (NTSB), an investigatory board for aviation accidents in the United States, determined that 'the probable cause of the accident was the flight crew's failure to use the taxi checklist to ensure that the flaps and slats were extended for takeoff.' [8] This shows that even though checklists have shown to improve safety of the aircraft, there are other measures that aviation regulatory bodies are required implement, to avoid situations where the crew may completely ignore safety procedures and systems.

2.3 Formal Methods

Formal methods is a mathematical technique that can be used towards the verification of a system, that could either be a piece of software or hardware. Therefore, this can be used to verify correctness of all the inputs in a system. [9] Hence, as this project is dealing with safety, it would be beneficial to use formal methods for testing and verification.

An example of where formal methods is used within aviation is by Airbus, where it was used during the development of the Airbus A380. Formal methods was used to test the A380 for proof of absence of stack overflows and analysis of the numerical precision and stability of floating-point operators to name a few. [10]

2.4 Solution Stack

- There would be around 3 main components to this tester
 - Formal Model
 - Flight Simulator plugin
 - Checklist Tester (to connect the formal model and flight simulator)
- As VDM-SL is being used, it uses VDMJ to parse the model [11]. This was a starting point for the tech stack, as VDMJ is also open source.

¹Aircraft Flight Manual - 'The Aircraft Flight Manual produced by the manufacturer and approved by the CAA. This forms the basis for parts of the Operations Manual and checklists. The checklist procedures must reflect those detailed in the AFM.' [6]

• VDMJ is written in Java [11], therefore to simplify implementing VDMJ into the Checklist Tester, it would be logical to use a Java virtual machine (JVM) language.

2.4.1 Formal Model

- There were a few ways of implementing the formal model into another application
- Some of these methods were provided by Overture [12]
 - RemoteControl interface
 - VDMTools API [13]
- However, both of these methods did not suit what was required as most of the documentation for RemoteControl was designed for the Overture Tool IDE. VDMTools may have handled the formal model differently
- The choice was to create a VDMJ wrapper, as the modules are available on Maven

2.4.2 Checklist Tester

JVM Language

- There are multiple languages that are made for or support JVMs [14]
- Requirements for language
 - Be able to interact with Java code because of VDMJ
 - Have Graphical User Interface (GUI) libraries
 - Have good support (the more popular, the more resources available)
- The main contenders were Java and Kotlin [15]
- Kotlin [15] was the choice in the end as Google has been putting Kotlin first instead of Java. Kotlin also requires less boilerplate code (e.g. getters and setters) [16]

Graphical User Interface

- As the tester is going to include a UI, the language choice was still important
- There are a variety of GUI libraries to consider using
 - JavaFX [17]
 - Swing [18]
 - Compose Multiplatform [19]
- The decision was to use Compose Multiplatform in the end, due to time limitations and having prior experience in using Flutter [20]
- Compose Multiplatform has the ability to create a desktop application and a server, which would allow for leeway if a server would be needed

2.4.3 Flight Simulator Plugin

- There are two main choices for flight simulators that can be used for professional simulation
 - X-Plane [21]
 - Prepar3D [22]
- X-Plane was the choice due to having better documentation for the SDK, and a variety of development libraries for the simulator itself
- For the plugin itself, there was already a solution developed by NASA, X-Plane Connect [23] that is more appropriate due to the time limitations and would be more likely to be reliable as it has been developed since 2015

Chapter 3

Design/Implementation

3.1 Components

The best way to view the design and implementation of this project is by splitting up the project into multiple components. This has been useful for aiding in planning the implementation, as a result making being efficient with time and requiring less refactoring. The planning allows for delegating specific work tasks, and making the project modular. A benefit of making this project modular is improving the maintainability of the codebase, and allowing for future upgrades or changes, for example, using a different flight simulator for testing.

Figure 3.1: Abstract layout of components

Each of the components in Figure 3.1 will be covered in detail in this chapter.

3.2 Formal Method

Formal modelling is the heart of the logic for testing checklists in this project and is created using VDM-SL. The formal model is the logic behind the actions of running through a checklist and checking if the checklist has been completed in the correct manner.

To be able to check that the checklist has been properly completed, the formal model keeps track of aircraft states, such as what state each switch in the aircraft is in; and the state of the checklist, such as what steps in the checklist has been completed.

As there are invariants, pre-, and post-conditions, which are used for setting well-formedness conditions for types or functions, provide type and input safety, which will result in an error when broken. This is useful to make sure that the actions taken when completing the checklist is done correctly, such as making sure that a switch that may have 3 possible states is moved in properly, such as moving from off, middle, to on in order, rather than skipping from off to on. The cases where errors would occur is when these well-formed conditions are broken, which can be a sign that the checklist has been completed incorrectly, such as when the checklist is not completed in order, could signify that a step in the checklist failed, which could mean that the step in the checklist is problematic.

Testing

Making sure that the formal model does not have well-formed conditions that can be broken by the formal model itself is important, as the goal of the formal model is to have a rigorous specification that is verifiable.

Since *VDMJ* version 4.5.0, the VDM interpreter has included the *QuickCheck* tool, [24] which is an automated testing tool to prove and find counter examples to specifications. [25]

There were multiple counter examples that was produced by QuickCheck that aided the development of the formal model, as the qc^1 command in VDMJ every time a new function was created to find potential counter examples and fix them. Checking every time when creating a new function was useful as it would avoid having to refactor more of the model.

3.3 Checklist Tester

The Checklist Tester is what provides a Graphical User Interface (GUI) for defining checklists to be tested, and to run the tests on the checklist. It is also responsible for connecting the Formal Method and the Simulator Connector Plugin together.

3.3.1 Designing

Creating an interface design before creating the GUI is useful as it is a form of requirements for the code.

Figma was used to create the design for the GUI as there is support for plugins and having a marketplace for components. This saved a lot of time in designing as Google provides components for Material 3^2 and a plugin for creating a colour scheme for Material 3.

Having this design was useful as it aided in understanding what parts of the GUI could be modular and reused, kept the feel of the design consistent, and helped memorize what parts of the GUI needed to be implemented.

The final design for the interface can be seen in Figure 3.2, where the components at the top are reusable modules, and the rest below are sections of the application that the user can navigate through.

Limitations of Figma

There were some limitations when working with *Figma*, one of them being that the components created for *Material 3* did not include all the features that are available in the *Compose Multiplatform* Framework.

This can be seen in the 'Simulator Test' screen at the bottom of Figure 3.2, where there is not an option for leading icons [26] in each of the list items, and therefore had to be replaced with a trailing checkbox instead. However, *Figma* allows for comments to be placed on the parts of the design, which was used as a reminder to use leading icons in the implementation of the design.

Another limitation of Figma is that in Figure 3.2, the title of the screen in the top app bar [27] is not centred, this is because the auto layout feature in Figma works by having equal spacing between each object, rather than having each object in a set position. However, this is not detrimental to the design, it is just obvious that the title is not centred in the window.

3.3.2 Compose Multiplatform

Setup

To set up *Compose Multiplatform*, the *Kotlin Multiplatform Wizard* was used to create the project as it allows for the runtime environments to be specified (at the time of creation, Desktop and Server), automatically generating the *Gradle* build configurations and modules for each runtime environment, for the specific setup.

 $^{^1\}mathrm{The}$ command to run QuickCheck on the formal model in VDMJ.

 $^{^2\}mathrm{Material}$ 3 is a design system which is used in Compose Multiplatform UI Framework.

Figure 3.2: Design for the Checklist Connector GUI in Figma

Implementation

Planning was important when implementing as *Compose* is designed to use modular components, otherwise a nested mess would occur as *Compose* is designed to have *Composable*³ objects passed into another *Composable* object. Therefore, due to how *Kotlin* is designed with functions, there will be function nesting occurring naturally. To aid in readability of code due to the nesting functions, the *Composable* objects are split into separate *Composable* functions. An example of this is in Listing 3.1, where instead of 10 *Composable* functions being nested in the Content() function, the items in the list (LazyColumn is used for creating lists) is split to a separate function, ActionItem(), as a result making the maximum amount of nested functions to 5 for all functions. Another benefit is that it allows for the ActionItem to be reused if desired, making the code modular.

Voyager [28] was used to handle the navigation of the application as it handles replacing previous navigation screens, and allows for inserting data into the navigation screens. This is as Voyager has integration with Koin [29][30], which is a library that specifically handles dependency injection. Using Koin allowed for data to be fetched from the database and to handle asynchronous functions, such as running VDMJ and sending instructions to the flight simulator.

3.3.3 Storing Data

SQLDelight was used to handle the database as it creates typesafe Kotlin application programming interfaces (APIs) to communicate to the database. It was specifically chosen as it provides support for Compose Multiplatform [31], making implementing SQLDelight into the project easier.

A benefit of using SQLDelight is that it only allows for database queries to be written in SQL, allowing for more complex, and more control of SQL queries. It also provides 100% test coverage [32] which is necessary to ensure that the database will not cause artefacts to the results.

The choice of relational database management system (RDBMS) to complement SQLDelight was SQLite as it allows for the database to run within the application, rather than running on a separate server, either remotely or through a containerized instance using something like Docker [33]. As a result, this avoided spending extra time implementing the server and adding extra complexity due to requiring additional dependencies, which would also add extra maintenance overhead to the project.

Designing the Database

The database could be looked at as having 2 sections, with relationships in mind between the two sections, to fulfil of the objectives, as it will allow tracking of the checklist tests that will be run, as a result being able to provide detailed statistics of the test. These relationships can be seen in the entity relationship diagram in Figure 3.3.

One of the sections is for user inputs to control the tests. The *Project* table handles creating separate aircraft, or it could be used for separate iterations of Quick Reference Handbooks (QRHs). Then the *Procedure* and *Action* table handles defining steps/actions in a checklist/procedure.

The other section of the database would be providing test results for each of the checklists, which are stored in the *Test* and *ActionResult* tables.

Expanding on the relationships between each table in Figure 3.3, the reasons for these relationships is to allow for segregation of data and the ability to associate test data with what checklist was tested.

Linking into Compose Multiplatform

Compose Multiplatform has support for different runtime environments which should be taken into account when adding *SQLDelight* to *Compose Multiplatform*. However, as this project is only being developed for Desktop, the *JVM SQLite* driver is the only one necessary to implement.

However, to improve maintainability of the code, the functions of the database was written in the shared/commonMain module (a shared module that is accessible to multiple runtime environments).

 $^{^3\}mathrm{A}$ Composable is a description of the UI that will be built by Compose Multiplatform

```
@Composable
1
    override fun Content() {
2
        // Content variables...
3
4
        Scaffold(
\mathbf{5}
             topBar = {/* Composable content... */},
6
        ) {
7
             Column(/* Column option parameters... */) {
8
                 Box(/* Box option parameters... */) {
9
                      LazyColumn(/* LazyColumn option parameters... */) {
10
11
                          item {
12
                               Header()
13
                          }
14
15
                          items(
16
                               items = inputs,
17
                               key = { input -> input.id }
18
                          ) { item ->
19
                               ActionItem(item)
20
                          }
^{21}
                      }
^{22}
                 }
23
            }
^{24}
        }
25
    }
26
27
    @Composable
^{28}
    private fun Header() {
29
        Text(text = "Edit Actions")
30
    }
31
32
    @Composable
33
    private fun ActionItem(item: Action) {
34
        Column (/* Column option parameters... */) {
35
             Row(/* Row option parameters... */) {
36
                 Text(text = "Action ${item.step + 1}")
37
38
                 IconButton(/* IconButton definition parameters... */) {
39
                      Icon(
40
                          Icons.Outlined.Delete,
41
                          // Rest of Icon options...
42
                      )
43
                 }
44
             }
45
46
             Row(/* Row option parameters... */) {
47
                 OutlinedTextField(/* TextField definition parameters... */)
48
49
                 OutlinedTextField(/* TextField definition parameters... */)
50
             }
51
52
             HorizontalDivider()
53
        }
54
    }
55
```

Listing 3.1: Example of modular code in Compose

Figure 3.3: Entity Relationship Diagram for the database in Checklist Connector

This would be useful if there was a need for adding Android and/or iOS support for this project as some designers may want to run the tests on a tablet.

Handling the database was done by implementing two modules. One module is the io.anthonyberg..connector.shared.database module, used to handle SQLDelight API calls only; meaning no conversion of types, functions are only accessible internally within the io.anthonyberg.connector.shared module.

The other module is the Software Development Kit (SDK) that handle type conversions, such as Int to Long, and can handle multiple tables, such as *TestTransaction* SDK that handles calls to multiple tables when a test is run in the flight simulator.

The separation of these modules was also done to have unit testing in mind because it will make it easier to debug if a problem is due to how SQLDelight transactions are handled, or if there are type conversions errors occuring.

3.3.4 VDMJ Wrapper

VDMJ is written in Java, and it is free open source software that is accessible on GitHub. This means that VDMJ can be used within any projects as long as the licence is followed. It is important to follow for ethical and legal reasons, as not following the licensing would result in breaking copyright law. However, it may not specifically break Newcastle University's ethics, it would break the ethos behind GPLv3 and free open source software.

The licence VDMJ uses is the GNU General Public License v3 (GPLv3) [34][35]. This means that as VDMJ is being used as a library, the code for this project has to be licensed with GPLv3 or any GPLv3 compatible licence [36].

Implementing VDMJ

VDMJ has packages available on Maven Central⁴ making adding it as a dependency simple as it would require to be specified within the *Gradle* build configurations. The package used was dk-.au.ece.vdmj:vdmj with version 4.5.0, however, initially when implementing VDMJ, 4.5.0-P was used accidentally, and it led to the rabbit hole of debugging why imports were not working, and it was found that the -P versions of VDMJ is not suitable to be used when being implemented intentionally a project.

The initial method of implementation was to use a Ktor server that would run alongside the desktop application, where communication between the desktop application and the server would be handled through Representational State Transfer (REST) API calls. However, this was unnecessary as the *interactive* mode of VDMJ was able to run on the desktop application itself. But using Ktor was useful for debugging and testing using as VDMJ commands could be run through an API route.

The major hurdle within implementing VDMJ as a wrapper was fetching the outputs that VDMJ sends to the console. This was implemented by creating a new VDMJ console handler ConsolePrintWriter, that handles writing to *stdout*, which is from the com.fujitsu.vdmj. \rightarrow messages package. This then gets used to replace the Console.out and Console.err, from the same VDMJ package, which will store the outputs to the console into a variable instead.

Parsing commands into the VDMJ interface was more difficult as it required using Java functions⁵ to act as if the program wrote something directly into the VDMJ interactive console. Figure 3.4 shows a simplified flowchart of how inputs are handled. A PipedInputStream object was created, that gets connected to a PipedOutputStream object by passing the latter object in as a parameter. The PipedOutputStream is then used to pass inputs into PipedInputStream. The PipedInputStream handles sending inputs to the VDMJ console. However, to be able to write to these streams, a BufferedWriter, which is used to send inputs, is created by passing the PipedOutputStream with a bridge OutputStreamWriter that encodes characters into bytes. For VDMJ to be able to read the input streams, the PipedInputStream gets parsed through a bridge,

 $^{^4\}mathrm{Maven}$ Central is a repository that stores dependencies required to build projects

⁵The objects created here are provided by the java.io package.

 $\verb"InputStreamReader" that converts bytes to characters, and then allows VDMJ read these characters through a BufferedReader.$

Figure 3.4: Flowchart of VDMJ Input/Output Stream handling

Handling VDMJ Command Outputs

When running a command in the VDMJ, it will produce an output as a string for the returned variable in the function that was executed.

To handle these strings, *Kotlin* string manipulation was used, similar concept to *Regex*, to decode the string and convert the string into correct types and store them in specific types in the formal specification, recreated in *Kotlin*.

The types recreated from the formal specification were the records types. This was done by using *Kotlin* data classes, which had functions implemented with the purpose of convert the stored types in *Kotlin* to an identical *VDM-SL* representation of the values in that type.

3.3.5 Connecting to the Flight Simulator

X-Plane Connect (XPC) was used to connect the desktop application to the flight simulator. X-Plane stores values of the aircraft states in what they call 'datarefs'. XPC allows to use these datarefs in external programs through libraries that complement the plugin used in X-Plane. The features that XPC brings is the ability to read data from the simulator, override dataref values, and execute other commands that can manipulate certain switches of the aircraft, where otherwise unable to by changing the value of the dataref.

Before running commands through XPC in the Checklist Tester, a check was run to verify that the X-Plane was running to avoid exceptions being thrown by XPC if it was not able to connect to the flight simulator.

When running the tests, each step in the checklist (referred to as 'action' in the logic implemented with XPC below) would go through an order with XPC. The first step is to fetch the initial state of the action in the simulator. Then, artificial delay is added before doing the action in the flight simulator, to imitate delay of the crew's lag between reading the step of the checklist and doing the action. Finally, XPC will execute the action in the flight simulator and get the final state of the action's sate in the flight simulator. Then in the Checklist Tester, it checks if the goal of the action was achieved in the final state.

Whilst running these actions in XPC, the initial state and time, and final state and time is recorded on the database to be used for the results of the test. These actions of running the XPC commands and storing the data on a database is run asynchronously to prevent the GUI from freezing as the application is waiting for a function to complete. This avoids misleading the user that the application has crashed, whilst allowing for test running animations within the GUI to continue being shown, making it look nicer.

3.3.6 Testing

Gradle provides testing integration, which allows for unit tests to be run through *Gradle*, with a command, in GitHub Continuous Integration for commits and packaging, or before building a complied application.

JUnit 5 was used for testing as other development tools provide integration with JUnit, such as integration with IntelliJ to view code coverage.

The testable components in this project are mostly backend modules as the GUI is difficult to write unit tests for there are not a lot of tools for testing *Compose* components, and testing the GUI would be an inefficient use of time as it is not the focus of this project.

For the backend, unit tests were written for the database and the dependency injection. Koin provides tools that allow unit tests to be automatically generated, as a result meaning it was worth the time to implement tests for dependency injection. The ethos when writing unit tests was to try and find exploits, act as a user who may mishandle inputs, and stress test functions that were developed.

Testing for Resource Usage

The application was tested using the *Profiler* tool provided by IntelliJ IDEA 2024 (Ultimate Edition) to find potential memory leaks and CPU intensive functions.

One problem was found which was the initial versions of the VDMJ wrapper that was created. The initial version did not use interactive mode, which resulted in VDMJ reinitializing each time a command was executed, resulting in a slight memory leak and a massive memory write usage.

3.4 Simulator Connector Plugin

3.4.1 Creating Maven Package

The XPC Java library is not published on a public Maven repository. There has been a pull request that was merged into the *develop* branch that provides Maven POMs [37]. However, the maintainer of the project, at the time, did not have enough time to figure out the process of publishing the package to a Maven repository [38].

Therefore, an alternative had to be found to implement the XPC library and there were a few attempts made, before remaking the build files and publishing the library onto GitHub's Maven repository.

The first tool found was Jitpack [39], which in theory makes it simple to publish to their own public Maven repository, as the requirements to publish the package was to input a desired GitHub repository and search if one has already been created on JitPack. If it has not been, JitPack will build and publish a desired version of the project. However, due to the structure of the XPC repository, JitPack was unable to locate the build tools (Apache Maven in this case) as JitPack only searches the root directory of the repository for the compatible build tools; XPC's build tools was in the Java/ directory.

The next step was to look if Gradle was able to handle building and implementing libraries from a GitHub repository, to which there is the gitRepository function [40]. It was a bit problematic trying to figure out how the gitRepository function worked as there is not a lot of documentation provided for it, and the documentation provided was ambiguous on how to define the directory where the Java library is located in the Git repository. However, as XPC was only built with Maven, Gradle was unable to add the dependency to the project as gitRepository only works with Gradle builds [41].

Therefore, as a temporary solution, implementing the library was resorted to using the Jar files provided with XPC and adding the dependency to Gradle. But this caused future maintainability

problems as updating the XPC library would require downloading the Jar file manually and replacing the previous version. It also results in other tools being unable to check if there is a new version of XPC available.

This temporary solution was later fixed by creating a fork of XPC and implementing *Gradle* build files. As there already are *Apache Maven* build files for the Java library, the gradle init command could be used to automatically generate *Gradle* build files based on the *Apache Maven* build files [42]. There was still some configuration required for the *Gradle* build files as the previous *Apache Maven* configuration was not properly implemented, resulting in fixing local dependencies and splitting up the library into their respective package groups.

Continuous Deployment of the Maven Package

To be able to use the new package created with *Gradle* and publish them, GitHub provides tools to publish *Gradle* projects automatically. This required defining in the build files on where *Gradle* can publish the packages. This was combined GitHub's Gradle Continuous Deployment template to publish the package, with the only change to the template being defining the working directory to be the Java/

3.4.2 Submitting a Pull Request

- Adding the Gradle build tools can be seen as being helpful for others, as it would allow for the XPC library to be added as a dependency, especially if the NASA Ames Research Center Diagnostics and Prognostics Group were to add it to the GitHub repository, it would mean that it would be easier for people to access Maven Packages for XPC
- Therefore, to help improve the experience for other people who would want to develop with the XPC Java library, it would be logical to submit a pull request
- But it did mean making sure that the contribution would be perfect and not contain problems

Testing

- The XPC Java library includes a JUnit 4 test, however, implementing this with Gradle proved useless, as it was not able to get the results from the tests, which would be bad for not being able to catch problems with new builds
- Therefore, the tests were updated to JUnit 5, where most of the changes were adding asserts for throws [43] 6

GitHub

- Made sure to add generated build files to .gitignore
- Changed the URL of the repository in Gradle to NASA's repository so that the Maven package can be published correctly on the GitHub repository
- From the beginning anyways, made sure to have insightful commit messages
- Submitted the pull request stating the changes made⁷

3.5 Scenarios

To be able to test if the objectives were met, QRHs can be used to find a potential list of checklists to test for. This can also be done by looking at previous accident reports that had incidents related to checklist as they provide problems related to the checklist, for example the US Airways Flight 1549 accident report includes the checklist used in the appendix [4]. With these checklists, they can be implemented to the Checklist Tester tool see if it will detect problems within the checklist.

⁶The commit including the changes to the tests can be viewed here: https://github.com/smyalygames/ XPlaneConnect/commit/e7b8d1e811999b4f8d7230f60ba94368e14f1148

⁷https://github.com/nasa/XPlaneConnect/pull/313

Chapter 4

Results

4.1 Final Prototype

4.1.1 Formal Model

- The model is mostly designed to imitate a Boeing 737-800, as the types modelled, have user inputs which are different from other aircraft types
 - For example, the Airbus A320 has push buttons whereas they are not there on the 737-800
 - However, further user input types could be added to the model and as a result, further aircraft types could have their procedures run through the formal model
- The **Procedure** type makes sure that the items on the procedure is completed in order, and if a step is missed, that would result in an invariant failure, resulting in the checklist test failing

4.1.2 Checklist Tester

- The main features of GUI have been completed, it has all the sections desired
 - Projects can be created to split up different aircraft or revisions of checklists
 - Procedures can be created and tested
 - These procedures get tested in the flight simulator automatically and gives the results of how the procedure has been doing in real time

4.1.3 Setting up Tests

- Each test is set up by defining each action in the procedure, on the Procedure screen
- To be able to define each action is supposed to do, it uses the Dataref variables in X-Plane, which is what stores the state of the aircraft. Each switch has their own unique Dataref
- In the checklist tester then, each action asks for a Dataref and a desired goal value
- Some Datarefs are read only, but there are other Datarefs for the item desired, but are only 'command's, which can only be called and not have its value changed; this can be run by setting the desired goal value to be -988 (because XPC uses that value)

Running Tests

- Tests are run by connecting to the flight simulator, X-Plane
- The tester goes through each action in the procedure one by one and waits for the current action to complete before proceeding on to the next one

• The checklist tester is not advanced enough to be able to control fly the aircraft; hence the tester would be able to engage autopilot first, or control the aircraft themselves, where the checklist tester would be acting like a first officer

Storing Test Results

- There is a database storing the results of each of the tests
- Each tests store

Time taken for each of the actions in the procedure to complete

Start state for the state that the action in the procedure was at

End state for the state that the action in the procedure finished the item at

Overall test time Stores the time taken from when the test started to when the test ended

• This gives feedback/statistics for the checklist designers to find areas of improvement on the procedure, such as one action in the procedure taking too long, may point out a potential flaw to the designer and as a result aid finding potential alternative options for that step in the procedure

4.2 Problems Found

4.3 LOC?

4.4 Reflection

4.4.1 Planning

Gantt Chart

Used Gantt chart to create a plan for what would be needed from this project

Pros:

- Was useful for the first part because it set expectations of what was needed and how much time there was to complete them
- Helped visualize the different components of the project
- Helped in the beginning being accompanied by a Kanban in Leantime¹

Cons:

- Was not detailed enough, and a design document would have been useful to accompany the Gantt chart for each section
- The lack of detail was not helpful when falling behind as having attention deficit hyperactivity disorder (ADHD) added to the burden of feeling like each section was a massive project
- Leantime's claim for being 'built with ADHD [...] in mind' felt misleading as navigating through it felt worse than using the front page of Stack $\rm Overflow^2$
- Todoist³ was a good alternative though

GUI Design

Figma was very useful in implementations as

Pros:

• It helped with timing and knowing what to do

¹https://leantime.io/

²https://stackoverflow.com/

³https://todoist.com/

- Made things feel manageable as it was split up to different sections
- Meant features will not be forgotten

Cons:

- Certain features being too simple and annoying to use
- A bit of a learning curve for using other components, compared to using plugins

4.4.2 Implementation

Checklist Tester

- Implementing the GUI was useful to split up the sections required for the project and having a goal for what to be done
- However, a bit too much time was spent on creating a GUI when it could have been used for development
- It was useful for motivational reasons to feel like something materialistic has been produced rather than something theoretical
- Was originally intended to be used to interact with custom plugin for X-Plane as it would have been difficult otherwise

Connecting to the Flight Simulator

- Would have been more useful to search a bit further if there was another plugin available, as found Dataref Editor on the X-Plane docs, so could have looked for a similar plugin for connecting to X-Plane
- At first spent about a week developing a C++ X-Plane plugin from scratch, requiring to figure out sockets
- At the same time finding out XPC exists and having wasted that time
- However, it did teach me more about understanding how sockets work and more about C++ and setting up a project with CMake and adding packages with vcpkg

4.5 Time Spent

- Time spent was recorded using Wakatime, other than time spent researching, which had to be recorded manually, using Leantime
- The time spent on GUI is also time spent on connecting other tools such as the VDMJ wrapper, XPC, and the database

Figure 4.1: Time spent on sections of project (in hours)

Chapter 5

Conclusion

5.1 Changes

- Added the checklist manager which was not a part of the original objectives
 - Helped more to visualize the project
 - Aided in gathering statistics for how well the checklist performed
 - Using Kotlin helped speed up development, it simplifies parts of Java and omitted a lot of boilerplate code that is required in Java, such as setters and getters
- How the Formal Model would interact was modified
 - Initially was designed so that the formal model would complete the entirety of the checklist, however, it was not useful for interacting with the flight simulator
 - Modified the model to provide it would be similar to actions pilots can do in the cockpit
 - Therefore acts like Read Checklist \rightarrow Pilot Logic (VDM) \rightarrow Do Action (XPC)
- Originally was supposed to write an original plugin to connect to the flight simulator
 - Whilst creating the plugin, sockets were confusing and accidentally stumbled on the X-Plane Connect GitHub repository
 - This could have been prevented if a design document was created and time was spent researching for tools in obscure places

5.2 Objectives

- Most of the objectives were met
- One of the original objectives was to research pilot reaction times and how long it takes pilots to complete an action
 - However, not able to do that as there are too many factors that can affect a pilot's reaction time, such as age, experience on an aircraft, total experience, how far a button is from the pilot, etc.
- Objective 2.a. was met to an extent
 - Currently, the states of the aircraft monitored are only the actions specified in the test, in the checklist tester
 - There could be more variables that could be monitored. Such as engine fire, could monitor the engine temperature or thrust produced by engine
 - This would have required a substantial amount of planning as checklists do have conditional statements, for example 'If APU is available, then do Step 3 else do Step 4'

- Objective 2.b. was also met to an extent
 - Currently, this can be met by re-running the test multiple times manually
 - However, it is manual at this stage due to limitations of XPC and setting up the aircraft
 - The test data is stored on the database, hence test results can be analysed to see the consistency between each test
- The Checklist Tester does not currently run actions from the Formal Model due to implementing the functions from VDMJ being laborious
- Hence focus was put on XPC first, as it would produce direct results

5.3 What Next

The most important next steps to implement would be linking the formal mode, adding options of what parts of the aircraft to monitor

- Formal Model
 - Implemented either by creating an automatic wrapper. Done by either potentially linking the VDMJ LSP, or creating a plugin for VDMJ
 - Or doing string manipulation on the VDM results for each of the functions as a lot of it is copy and paste - can be bad practice as it requires a lot of hard-coded code
- Monitoring more of the aircraft
 - Done by adding options in the Checklist Tester for extra Datarefs to monitor
 - Modifying the Aircraft record type to include a states type that checks multiple times throughout the procedure if this state has violated a constraint or if the goal of the state has been achieved (e.g. Engine is no longer on fire)
- Expanding out of the scope of the objectives, conditional logic, such as if statements, to the checklist would be the next logical step
 - VDM-SL would be really helpful for this, as can be used to design logic to be used outside of Kotlin
 - This would allow for further automation of checklists, rather than only testing linearly, which at this current state would require writing the test multiple times
- Adding more detailed test results
 - Use analysis of previous test results to gain an understanding of the reproducibility of the procedure
 - Keep track of aircraft state, such as speed or altitude aiding in understanding if the procedure may impose a safety risk
